## Enhancing Syngas Conversion Selectivity with Dynamic Confinement in OXZEO Composite Catalysts

Scientists from the Dalian Institute of Chemical Physics (DICP) of the Chinese Academy of Sciences have reported for the first time the induction period in syngas conversion over an OXZEO composite catalyst, ZnCrO<sub>x</sub>-SAPO-17. During this period, a dynamic confinement develops within the SAPO-17 cage, which enhances the selectivity of ethylene and suppresses that of C<sub>4+</sub> hydrocarbons.

The study entitled "Dynamic confinement of SAPO-17 cages on the selectivity control of syngas conversion" was published in National Science Review on July 26.

Converting syngas, a mixture of hydrogen and carbon monoxide, into liquid fuels has been the focus of much academic and industrial research in the field. One promising alternative to traditional Fischer-Tropsch synthesis (FTS) is the OXZEO bifunctional catalyst concept, which offers a more effective solution to the challenge of selectivity encountered in FTS.

The OXZEO process, which involves the use of SAPO-34 zeotype and ZnCrO<sub>x</sub> oxides, has been shown to convert syngas into mixed light olefins ( $C2^{=}-C4^{=}$ ) with a selectivity of up to 80%. The high selectivity of this process is due to the disconnected CO/H<sub>2</sub> activation and C-C bond coupling on the two spatially separated active sites.

The selectivity of the OXZEO process can be

further modulated by the shape selective zeolitic pores and the morphology of the zeolites. For instance, zeolites with 8-member ring pores favor the synthesis of mixed light olefins, while zeolites with 10–12-member ring pores favor gasoline ranged hydrocarbons. Additionally, the channel structure and morphology of the zeolites can fine-tune the hydrocarbon distribution.

These findings demonstrate the potential of the OXZEO process as a promising technology for the efficient and clean utilization of carbon resources. Further research is needed to fully realize the potential of this technology and to find practical applications for it.

## Boosters Show Promise Against Omicron Variant

A study published in the July 21 issue of the *New England Journal of Medicine* has found that the current vaccines against the coronavirus disease 2019 (COVID-19) may not be as effective against the omicron variant and its subvariants (doi: 10.1056/NEJMc2206900).

In this study, a research team led by George F. Gao at the Institute of Microbiology of the Chinese Academy of Sciences (IMCAS) assessed the neutralizing antibody levels in individuals who received either inactivated virus vaccines or the protein-subunit vaccine ZF2001. They found that all vaccinated groups had lower neutralizing antibody levels against the Omicron variant compared to the prototype strain. The findings indicate substantial immune escape for the omicron

subvariants and suggest that current vaccines may not be adequate against the rapidly emerging new variants of SARS-CoV-2.

The study also found that increasing the interval between the second and third doses of the ZF2001 vaccine could significantly increase neutralizing antibody titers against the omicron subvariants. In vaccinees with a  $4\sim6$ -month interval between second and third doses, neutralizing antibody titers were nearly ten times higher against the prototype isolate and 30 times higher against the omicron subvariants, compared to vaccinees with a 1-month interval between doses.

Despite these findings, the rapid emergence of new variants makes it challenging to develop variantspecific vaccines. The study suggests that a better immunization strategy for current vaccines, such as administering multiple booster doses and immunematuration methods, could help increase neutralization levels of omicron subvariants. However, further research is needed to develop effective vaccines against the evolving SARS-CoV-2 variants and to ensure that global populations are adequately protected against the ongoing COVID-19 pandemic.

## Yak's Genomic Signatures for High-altitude Adaption

For the folks who suffer severe altitude sickness when travelling to the Qinghai-Tibetan Plateau or other highaltitude sites, the wild yaks, capable of keeping running and running on these wild lands, might be a top envy target. You may be awed by the prime beauty of these herd animals caught at first sight, or you may struggle to catch your breath when swearing feebly – What the heck! How these beasts do that!

A newly reported study from *Nature Communications* reveals some unique endothelial cells in yak lungs, which are not to be seen in domestic cattle. These cells were found to help forge elastic lungs for the yaks.

It is known that the yak's blood, lung, and heart systems have been evolved to meet the challenge at high altitudes. They can better withstand hypoxia because

they have higher hemoglobin content and red blood cell count. They have bigger lungs and hearts than those of age-matched domestic cattle. They also have more abundant blood vessels in the lung tissue. Yet, what exact genomic changes enable their high-altitude adaption remains to be explored.

Next-generation sequencing has proven to be a powerful tool for studying genomic changes. However, the limitation of the genome assembly using short reads makes it impossible to accurately detect the genomic changes that come at a big scale, such as deletions, insertions, duplications, and inversions.

Using the Nanopore technique for long reads and the Hi-C technology for genome assembly, the team successfully get two long-read genome assemblies of wild and domestic yak.

By comparing these long-read genomes with a high-quality reference genome of domestic cattle, researchers found that many genomic changes lie in the noncoding sequences, including promoter and untranslated regions (UTR), which usually regulate the expression of nearby genes. They suggested that the yaks may benefit from the genomic changes in the promoters of hypoxia-related genes.

They also identified a yak-specific endothelial cell subtype using single-cell transcriptome sequencing, a technique widely used for grouping cells with similar mRNA expression profiles. These unique cells can enhance the medial thickness of micro-vessels and the formation of elastic fibers in yak lungs.

Researchers believe that their findings would have important implications for understanding the physiological and pathological responses of large mammals and humans to hypoxia.

"These high-quality genomes and single-cell RNAseq data serve an important source for future research on bovine species," say the researchers.
